Problem Statement: How might we help elderly and immigrant communities plan for and prepare better before and during emergency situations like evacuations during wildfires?

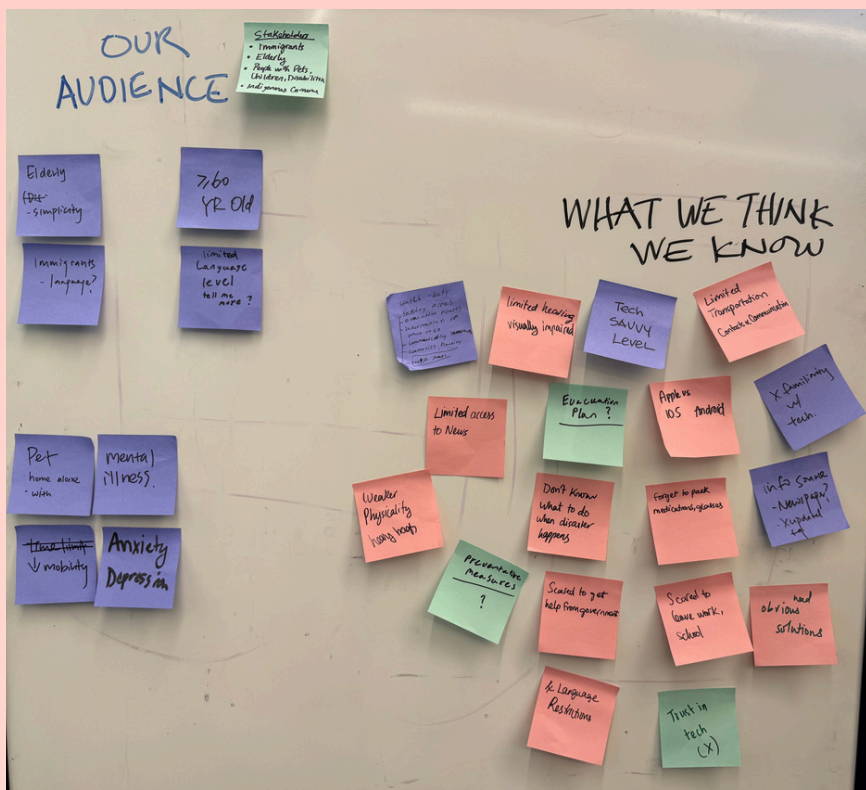

Audience: Elderly and immigrant communities.

Empathize and Define: We interviewed 18 people to understand our target group’s needs and problems. They felt as though they were not prepared for emergencies, their alert delivery systems were outdated and they did not get real time information fast enough.

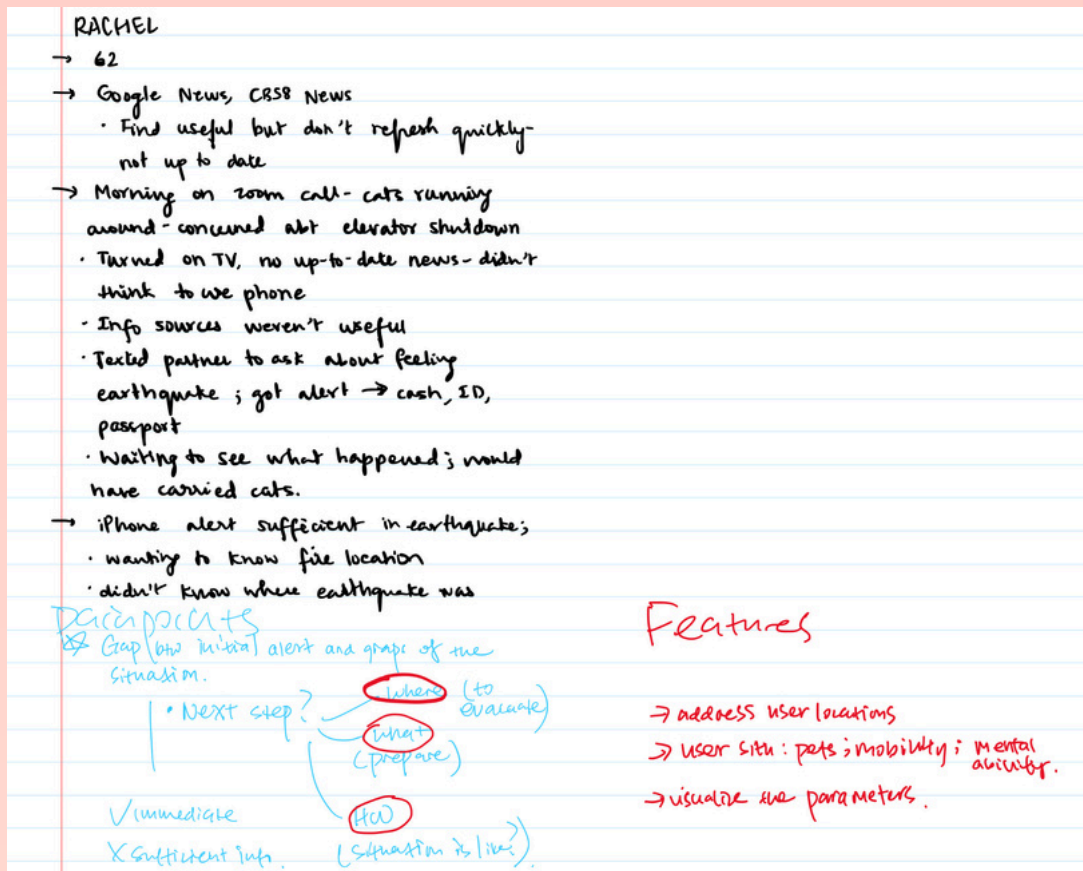

Ideate: We discussed the different pain points of our target group, primarily language restrictions and unfamiliarity with technology. We then began generating ideas like a decentralised network to share updates on new fires, and gamified learning to help spread awareness on the risks and unpredictability of wildfires.

Design Challenge: From ideation, we began narrowing our focus down to the “precognition” aspect of wildfire risk mitigation- how we could better predict the likelihood of fire occurrence, and help users prepare in case of emergencies.

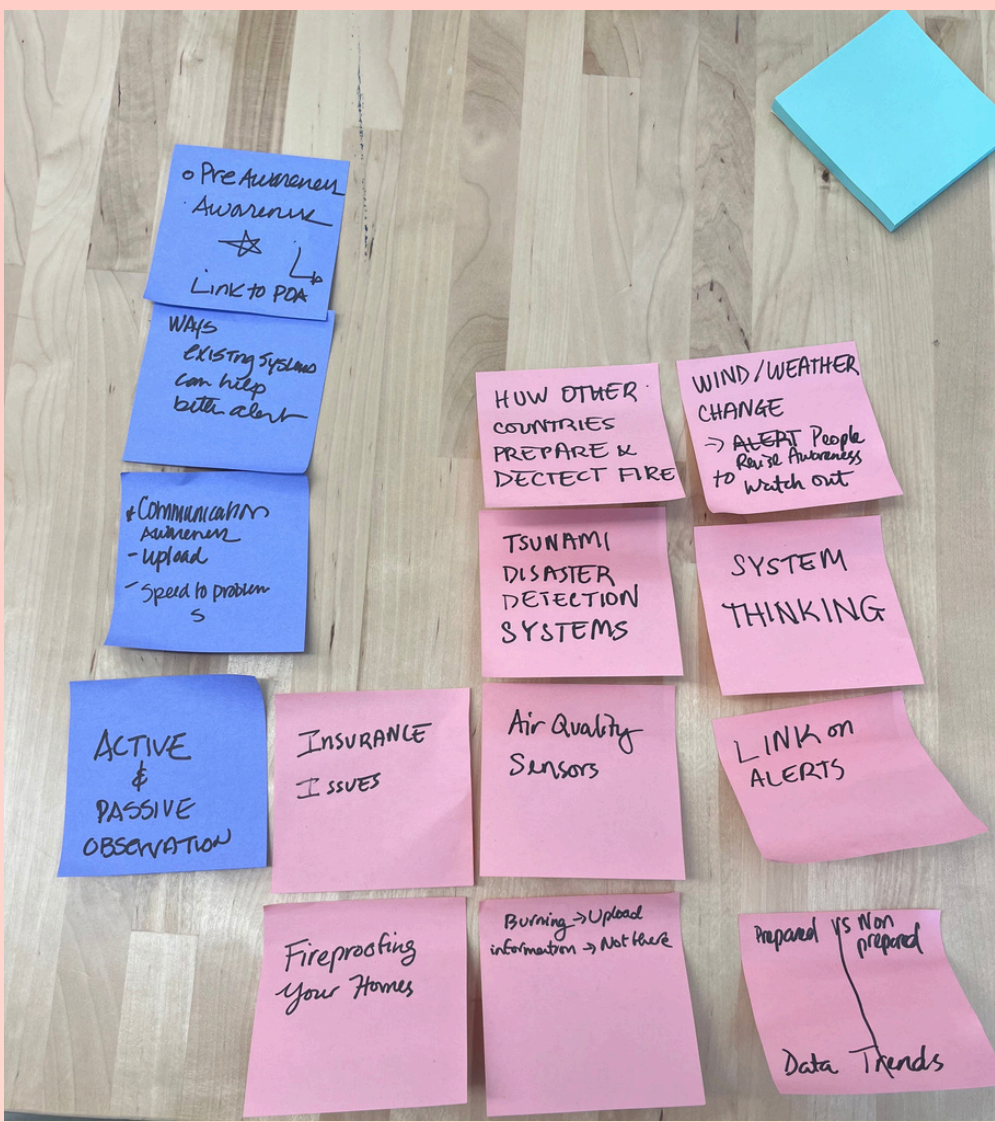

Concept Description: Our solution takes a two-pronged approach to the problem statement: an app interface that uses aggregate data to predict the probability of fires and alert users, and a campaign to reach our target groups through radio and social media marketing. We drafted a multifaceted campaign and app for elderly and immigrant communities. The app notifies users at the start of the predicted fire season to help them prepare a Plan of Action. It also notifies users of their evacuation plan during a potential emergency.
